

UNIT - 1Introduction to C

Features of C and its Basic Structure,
 Simple C programs.
 Constants Integer.
 Integer Constants.
 Real Constants.
 Character Constants.
 String Constants.
 Backslash Character Constants.
 Concept of an Integer and a variable.
 Rules for naming Variables and.
 Assigning Values to Variables.

- C programming language was developed by Dennis Ritchie in 1972.
- We will be learning C99 standard (ISO C)

CONSTANTS

A constant is an entity that doesn't change
 They are often called as literals.

TYPES OF CONSTANTSTYPES OF CONSTANTS

→ SECONDARY
 → Pointers
 → Array → String, and Structures
Unions → Enum
Labels → are linked to variables → functions.

PRIMARY CONSTANTS

1. Integer constants

A integer constant is a value a decimal, octal or hexadeciml number that represents an integral value.

→ R.D.C. [Integer constants] → values between limits
integers!

- Must contain at least 1 digit.
- must not have a decimal point.
- can be 0 +ive or -tive.
- commas or blanks are not allowed.
- Range: → -2147483648 +0 +2147483647

Ex → 426, +7.82, -18000, 27605

2. Real Constants

A constant with the combination of +ive, 0, +tive followed by a decimal point and the fractional part
 → No exponent → base value → with decimal points → with exponent → base value → with decimal points.

ROC a Real Constant

- A real constant must contain at least one digit.
- must contain a decimal point.
- can be +ve or -ve.
- Commas or blanks are not allowed.

Ex → +325.51, 126.0, -3276, +48.5792

3 Character Constant (either a character or a sequence of characters)
A character constant is a single alphabet, digit or special symbol enclosed within single inverted commas.

ROC a character constant

- must have one alphabet, number or special symbol.
- should be enclosed in single inverted commas.

Ex → 'A', 'I', '5', 'E' → 20.3

SECONDARY CONSTANTS

1 STRING CONSTANTS (string is a sequence of characters)
A string constant is a sequence of a sequencing of characters enclosed in double quotes.

ROC of a String Constant

- A string constant may consist of any number of alphabets, numbers or special characters.
- It must be enclosed in double quotes.

Difference b/w a character constant and string constant.

Character constant

A single character string has an equivalent integer value.

enclosed within single inverted commas.

Max length of a char const can be one character

A single character constant occupies one byte.

String constant

A single character string constant does not have an equivalent integer value.

enclosed within double inverted commas.

A string constant can be of any length.

A single string constant occupies two bytes.
"A" & "D".

Ex → "A", "5", "3"

"she is 10 years old."
"Ati", "361=1"

Backslash Character Constants

There are some types of characters that have a special type of meaning in the C language. These must be preceded by a backslash symbol so that the program can use the special function in them.

Meaning of Characters

Backspace

\backslash b and

New line

\n

Form feed

\f (newline)

Horizontal tab

\t (horizontal tab)

Carriage return

\r\n

Single quote

'

Double quotes

" (double quotes)

Vertical tabs

\v (vertical tabs)

Backslash

\

Question mark

\? (question mark)

Alert or Bell

\a (alert or bell)

Hexadecimal constant

\XN (hex)

Octal constant

\N (octal)

Backslash Characters

\b (backspace)

\f (newline)

\r\n (carriage return)

\v (vertical tab)

\t (horizontal tab)

\? (question mark)

\a (alert or bell)

\XN (hex)

\N (octal)

Variables

A variable is a name assigned to a memory space that may be used to store a data value.

Rules for naming variables#Rule No. 1

A variable name may include the alphabets, numbers and '_'. Special characters are not allowed.

#Rule No. 2

A variable name must not begin with a digit.

#Rule No. 3

A variable name may begin with a underscore, but by not to.

#Rule No. 4

C language is case sensitive.

So, Name, NAME, NaMe, NAME, all are different.

#Rule No. 5

Blanks or white spaces are not allowed.

Do not use long names for a variable.

#Rule No. 6

Don't use keywords to name your variable like print, switch, if, while, else etc.

Assigning value to a variable

To assign a value to a variable, we use an assignment expression.

Assignment expressions assign a value to the left operand.

Assignment Operators

Simple ($=$) performs the value of the right operand to the left operand.

Compound ($+=, -=, *=, /=, \% =, \ll =, \gg =, \&=$) performs an operation on both operands and give the result of that operation to the left operand.

Ex → name $\{ = Shreya;$
 Ex → index $\{ \#$
 Var = 5;

Types of compound assignment operators

- 1.) $\pm =$ First addition then assignment.
- 2.) $\mp =$ First subtraction then assignment.
- 3.) $* =$ First multiplication then assignment.
- 4.) $/ =$ First division then assignment.
- 5.) $\% =$ First modulus then assignment.
- 6.) $\ll =$ First bitwise left shift then assignment.
- 7.) $\gg =$ First bitwise right shift then assignment.
- 8.) $\& =$ First bitwise AND then assignment.

- 9.) $\oplus =$ First bitwise OR then assignment.
 10.) $\wedge =$ First bitwise XOR then assignment.

```
int main() {
    var = 5;
    var  $\pm$  2;
    printf("%d", var);
    return 0;
}
```

ANS → { (Value will get assigned at the time of assignment) }

→ { (Value we need to take will be taken) }

Scope of Variables

Scope: a block or a region where a variable is declared, defined and used and when a block or area ends, variable is automatically destroyed.

Types of Variables

Local

A variable that is declared inside the function or block is called 'local variable'.

```
syntax / main() {
    void fun() {
        int a = 10
        pf ("%d", a)
    }
}
```

Global

A variable that is declared outside a function or a block. It is accessible to all the functions.

Syntax of local variable

```
main() {  
    void fun() {  
        int a = 5;  
        printf("%d", a)  
    }  
    printf("%d", a)  
}
```

Since `a` is inside the region of the void `funk()` function, the second pair of statement cannot access it. So this will produce an error.

$a = 5$ → local variable
accessible only to void fun() function.

In addition to natural resources we should also consider
the need to protect basic human needs including
household water supply and sanitation, clean roads

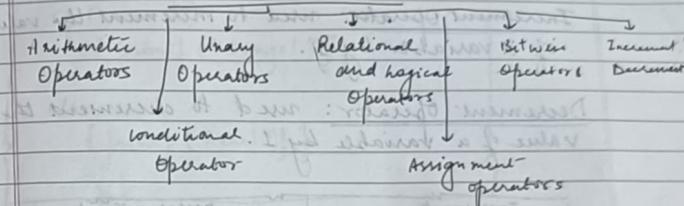

1) *Ardeola ralloides* - best alderleaf
2) *Ardeola ralloides* - white bellied
3) *Ardeola ralloides* - white bellied
4) *Ardeola ralloides* - white bellied
5) *Ardeola ralloides* - white bellied
6) *Ardeola ralloides* - white bellied
7) *Ardeola ralloides* - white bellied
8) *Ardeola ralloides* - white bellied
9) *Ardeola ralloides* - white bellied
10) *Ardeola ralloides* - white bellied

Question

• 111 •

Operators

TYPES OF OPERATORS

1. ARITHMETIC OPERATORS

- i) + Addition
 - ii) - Subtraction
 - iii) * Multiplication
 - iv) / Division
 - v) % Modulus (Remainder)

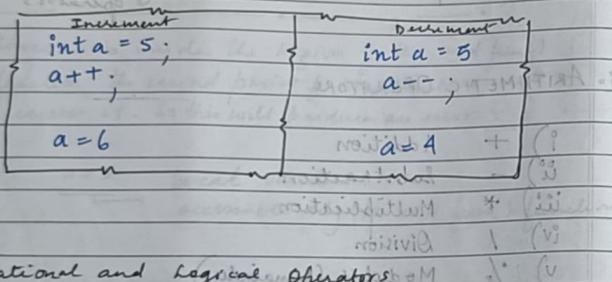

OPERATOR PRECEDENCE & ASSOCIATIVITY

Precedence	Operator	Associativity
Highest	$+$ $*$, $/$, $\%$	from left to right
Lowest	$+$, $-$	from left to right

2. Increment Operator and decrement Operators

Increment Operator: used to increment the value of a variable by 1.

Decrement Operator: used to decrement the value of a variable by 1.

3. Relational and Logical Operators

Relational Operators are used for comparing values.

They all return True or False.

- i) $= =$ equal to
- ii) \neq not equal to
- iii) \leq less than or equal to
- iv) \geq greater than or equal to
- v) $<$ less than
- vi) $>$ greater than

int a = 300, b = 2090;
if (a >= b)
{ printf ("Bingo!\n"); }
else
{ printf ("Aah!\n"); }

NOTE

Since a is smaller than b ,

so statement will be printed.

→ Aah!

Logical Operators: evaluates the conditions and returns a result.

- i) $\&\&$ AND → returns TRUE only when all cond. are T.
- ii) $\| \|$ OR → returns TRUE if any one cond. is True.
- iii) $!$ NOT → returns TRUE when cond. is False and vice versa.

4. Bitwise Operators

Performs bitwise manipulation.

- i) $\&$ AND
- ii) $|$ OR
- iii) \sim NOT
- iv) \ll Left Shift
- v) \gg Right Shift
- vi) \wedge XOR

i) & AND : It takes two bits at a time and performs AND operation.

$$\begin{array}{r} \text{Ex} \rightarrow 0111 \rightarrow 7 \\ \underline{0100} \quad 4 \\ \underline{0100} \quad 4 \\ \hline 7 \& 4 = 4 \end{array}$$

ii) OR : It takes two bits at a time and performs OR operation.

$$\begin{array}{r} \text{Ex} \rightarrow 0111 \rightarrow 7 \\ \underline{0100} \quad 4 \\ \underline{0100} \rightarrow 7 \end{array}$$

$$7 \mid 4 = 7$$

iii) NOT : Unary operator. complements each bit one by one !

$$\begin{array}{r} \text{Ex} \rightarrow 0111 \\ \rightarrow 1000 \end{array}$$

$$~7 \rightarrow 8$$

22 (v)
22 (vi)
22 (vii)
22 (viii)

iv) Left Shift << : If shifts the bit one by one to the left and trailing positions are filled with zero's.

$$\begin{array}{l} \text{char Var} = 3; \\ \text{Var} \ll 1; \\ \hline \text{---} (6) \end{array} \quad \left| \begin{array}{l} 0011 \rightarrow ? \\ \rightarrow 0110 \quad (6) \end{array} \right. \quad \begin{array}{l} \rightarrow 1110 \\ \rightarrow n \times 2^{\text{degree of shift}} \\ \rightarrow 1100 \end{array}$$

$$\begin{array}{r} \text{Ex} \rightarrow \text{var} = 60 \\ \text{var} \ll 4 \end{array} \quad \rightarrow \quad 60 \times 2^4 \rightarrow 60 \times 16 = (960)$$

v) Right Shift >> : If shifts the bits one by one to the right and trailing leading positions are filled with zero's.

$$\begin{array}{l} \text{char var} = 3; \\ \text{Var} \gg 1; \\ \hline \text{---} (1) \end{array} \quad \left| \begin{array}{l} 0011 \quad (3) \\ \rightarrow 0001 \quad (2) \end{array} \right. \quad \begin{array}{l} \rightarrow n \times 2^{\text{degree of shift}} \\ \rightarrow 1 \end{array}$$

$$\begin{array}{r} \text{Ex} \rightarrow \text{val} = 32 \\ \text{val} \gg 4 \end{array} \quad \rightarrow \quad \frac{32}{2^4} = \frac{32}{16} = (2)$$

vi) \uparrow XOR → When both are 1 or 0
then the result is 0. When both are different
then the result is also.

Bitwise XOR operator performs XOR function
bit by bit.

$$\begin{array}{rcl} 0111 & \rightarrow & 3 \\ 0100 & \rightarrow & 4 \\ \hline 0011 & \rightarrow & 3 \end{array}$$

$$7 \wedge 4 \rightarrow 3$$

5. Conditional Operator [?]

→ takes three operands

→ condition? Expression1 : Expression2;

char result;

int marks = 50

result = (marks > 33) ? 'P' : 'F';

→ P

6. COMMA OPERATOR (,)

→ can be used as a separator

$$\text{int } a = 3, b = 4, c = 8$$

→ comma operator returns the rightmost operand in the expression and it simply evaluates the rest of the operands and finally rejects them.

```
int var = (3, 4, 8);  
printf("%d", a);
```

→ 8

→ The comma operator evaluates all operands but assigns the value to the var variable of the last operand.

```
int var = (printf("Hello!", "Hello!"), 5;  
printf("%d", var);
```

→ Hello!
5

7. `sizeof()` determines the no. of bytes required to store the ~~to~~ data.

\rightarrow `int x;`

`sizeof(x);` \rightarrow 2

`Sizeof 5; 2`

`Sizeof char; 1`

`Sizeof float; 4`

`Sizeof double; 8`

`Sizeof long double; 10 - 12`

Operators in C + C++ = 20x 30x

based on no. of Operands

Unary (1 operand)

- Unary minus -

- Increment ++

- Decrement --

- Asym Not !=

- `sizeof()`

Binary (2 operands)

- Assignments

- Arithmetic

- Relational

- Bitwise operator

Ternary

(3 operands)

Conditional

operator (?)

TYPES OF DATA TYPES

1) Char

char variable - name = 'N';

range → Signed → -128 to +127

Unsigned 0 to 255

`sizeof(char) = 1 byte`

%c

2) float

→ float variable - name = 'value';

`printf("%f", variable_name)`

float can print correct values till 6 decimal points.

`sizeof(float) → 4 bytes`

%f

3) double

↳ double precision and bitwises are used

double variable - name = 'value'

written with dot or comma as decimal separator

`double → 16 digits → sizeof(double) → 8`

`long double → 17 digits → sizeof(long double) → 12`

int v;

int var = 4/9

Var > 0

$\text{size of } \text{int} = 2 \text{ bytes}$ → $\text{Var} < 0$

float

$\text{float } \text{var} = (\text{int}) \text{Var};$

INTEGER & FLOAT CONVERSIONS

1. $\text{int} \Rightarrow \text{int} = \text{int}$
2. $\text{float} \Rightarrow \text{float} = \text{float}$
3. $\text{int} \Rightarrow \text{float} = \text{float}$
 - ↳ If int is promoted to float then \Rightarrow operation is performed.

$$\left\{ \begin{array}{l} \text{float } a, b, c; \text{int } \text{c}; \\ S = a * b * c / 100 + 32 / 4 - 3 * 1; \end{array} \right.$$

Here the expression has various float and int terms. So, first the int terms will be promoted to float. Then the operations will be performed.

Then the result will be converted to int since variable assigned to the result is of int data type.

MIXED MODE EXPRESSION

Such an expression in which the two operands are not of the same data type is called a mixed mode expression.

TYPE CASTING
Converting \Rightarrow a data type of one variable to some other data type.

- 1) Implicit casting → done by compiler
- 2) Explicit casting → done by programmer.

Explicit Casting

Case I $\text{int} a = 10, b = 3;$ $\text{float } c = a/b;$

Output → $10/3 \rightarrow 3$ → int type operator

Case II $\text{int} a = 10, b = 3;$ $\text{float } c = (\text{float}) a/b;$

Output → $10/3 \rightarrow 3.33$ → float expression

Case III

$\text{int } a = 10, b = 3;$

$\text{float } c = (\text{float})(a/b);$

Type Cast Operator

The type cast operator converts the data type of the expression to the type specified by the type-name.

KEYWORDS

The keywords are words whose meaning has already been explained to the C compiler.

2. Keywords

auto	- double	- int	struct
break	- else	- long	switch
case	enum	- negligible	typedef
char	- extern	- return	union
const	- float	- short	- unsigned
continue	- for	- signed	void
default	goto	- sizeof	volatile
do	if	- static	- while

Character Input & Output

getchar()

To read a single character as input we use [getchar()] function.

char ch;

```
printf("Enter a character: ");
ch = getchar();
printf("Entered character: '%c\n'", ch);
return 0;
```

Output → Entering character: A
Entered character: A

putchar()

To output a single character we use the [putchar()] function.

```
char ch;
printf("Enter any character: ");
ch = getchar();
printf("Entered character: ");
putchar(ch);
return 0;
```

Output → Entering character: A
Entered character: A

Formatted Input and Output

1) `printf()` : used for displaying a single or multiple values in the form of output for the user end at the console.

2) `scanf()` : this is used for reading a single or multiple values in the form of input from the user end at the console.

3) `sprintf()`:

* returns pointer to string

* : reserved keyword

auto double float

break case long while

case char negative float (double)

[Unassessed] all new and alternate, arrays & pointers & structures

Scarf() - Syntax

`scanf ("%d" & variable name)`

(* : reserved keyword) {field}

int var; (* : reserved keyword = As)

(* : reserved keyword) {field}

`scanf ("%d" & var);`

(* : reserved keyword)

(* : reserved keyword)

* : reserved keyword ← string()

* : reserved keyword

Format Specifiers

%t tab space

%n new line

%d signed integer

%c character value

%f floating point value of a float

%lf floating point value of a double

%Lf long double

%s string

* : reserved keyword

`gets()` : used for reading a string from a user.

`puts()` : prints a string as taken from the user input on the console.

i) & AND : It takes two bits at a time and performs AND operation.

$$\begin{array}{rcl} \text{Ex} & \rightarrow & 0111 \rightarrow 7 \\ & & 0100 \quad 4 \\ & \underline{\quad} & \underline{\quad} \\ & & 0100 \quad 4 \\ & & \text{Final result} \end{array}$$

$$7 \& 4 = 4$$

ii) & OR : It takes two bits at a time and performs OR operation.

$$\begin{array}{rcl} \text{Ex} & \rightarrow & 0111 \rightarrow 7 \\ & & 0100 \rightarrow 4 \\ & \underline{\quad} & \underline{\quad} \\ & & 0111 \rightarrow 7 \end{array}$$

$$7 | 4 = 7$$

iii) ~ NOT : Unary operator. complements each bit one by one.

$$\begin{array}{rcl} \text{Ex} & \rightarrow & 0111 \\ & \rightarrow & 1000 \\ & & \text{Final result} \\ & \sim 7 & \rightarrow 8 \end{array}$$

$$\begin{array}{l} \text{Ex} \rightarrow 1100 \\ \rightarrow 0011 \\ \sim 1100 \rightarrow 0011 \\ \text{Final result} \end{array}$$

iv) left shift << : If shifts the bit one by one to the left and trailing positions are filled with zeros.

$$\begin{array}{l} \text{char var} = 3; \\ \text{var} \ll 1; \\ \rightarrow \boxed{6} \end{array}$$

$\begin{array}{l} 0011 \quad (3) \\ \rightarrow 0110 \quad (6) \end{array}$	$\rightarrow n \times 2^{\text{degree of shift}}$
---	---

$$\begin{array}{rcl} \text{Ex} & \rightarrow & \text{var: } 60 \\ & & \text{var} \ll 4 \\ & \rightarrow & 60 \times 2^4 = 60 \times 16 = \boxed{960} \end{array}$$

v) Right Shift >> : If shifts the bits one by one to the right and trailing leading positions are filled with zeros.

$$\begin{array}{l} \text{char var} = 3; \\ \text{var} \gg 1; \\ \rightarrow \boxed{1} \end{array}$$

$\begin{array}{l} 0011 \quad (3) \\ \rightarrow 0001 \quad (1) \end{array}$	$\frac{n}{2^{\text{degree of shift}}}$
---	--

$$\begin{array}{rcl} \text{Ex} & \rightarrow & \text{var: } 32 \\ & & \text{var} \gg 4 \\ & \rightarrow & \frac{32}{2^4} = \frac{32}{16} = \boxed{2} \end{array}$$

vi) \wedge XOR → When both are 1 or 0 then the result is 0. When both are different then the result is zero.
 Bitwise XOR operator performs XOR function bit by bit.

$$\begin{array}{rcl} 0111 & \rightarrow & 7 \\ 0100 & \rightarrow & 4 \\ \hline 0011 & \rightarrow & 3 \end{array}$$

$$7 \wedge 4 \rightarrow 3$$

5. Conditional Operator [?]

→ takes three operands

→ condition? expression1 : Expression2 ;

```
char result;
int marks = 50
```

```
result = (marks > 33) ? 'p' : 'f';
```

\rightarrow [P]

COMMA OPERATOR (,)

→ can be used as a separator

$$\text{int } a = 3, b = 4, c = 8;$$

→ comma operator returns the right most operand in the expression and it simply evaluates the rest of the operands and finally rejects them.

```
int var = (3, 4, 8);
printf("%d", a);
```

\rightarrow 8

* comma operator evaluates all operands but assigns the value to the val variable of the last or rightmost operand.

```
int var = (printf("Hello", "Hello"), 5);
printf("%d", var);
```

Hello!
5

7. `sizeof()` determines the no. of bytes required to store the ~~all~~ data.

→ `int x;`
`sizeof(x); 2`
`Size of 5: 2`
`Size of char: 1`
`Size of float: 4`
`Size of double: 8`
`Size of long double: 10 - 12`

Operators in C
based on no. of Operands

Unary (1 operand)

- Unary minus -
- Increment ++
- Decrement --
- Design-Not `!>`
- `sizeof()`

Binary (2 op)

- Assignments
- Arithmetic
- Relational
- Bitwise op.

Ternary
(3 operands)
conditional
operator (?)

TYPES OF DATA TYPES

1) char

char variable - name = 'A';
range → Signed → -128 to +127
Unsigned 0 to 255

`sizeof(char) = 1 byte`

I.C.

2) float

→ float variable - name = 'value'
`printf("8.16f\n", variable_name)`

float can print correct values till 6 decimal points.

`sizeof(float) → 4 bytes`

3) double:

double variable - name = 'value'

double → 16 digits → `sizeof(double) → 8`
long double → 19 digits → `sizeof(long double) → 12`

int v;

int var = 4 / 9

Var = 0

size of (int) = 2 bytes

%d

INTEGER & FLOAT CONVERSIONS

1. int ± */ int = int

2. float ± */ float = float

3. int ± */ float = float

\hookrightarrow if int is promoted to float - then \Rightarrow op is performed.

```
float a, b, c; int s;
s = a * b * c / 100 + 32 / 4 - 3 * 1.1;
```

Here the expression has various float and int terms. So, first the int terms will be \Rightarrow promoted to float. Then the operations will be performed.

Then the result will be converted to int, since variable assigned to the result is of int data type.

MIXED MODE EXPRESSION

Such an expression in which the two operands are not of the same data type is called a mixed mode expression.

TYPE CASTING

Converting of a data type of one variable to some other data type.

- 1) Implicit casting \rightarrow done by compiler
- 2) Explicit casting \rightarrow done by programmer.

Explicit Castings.

Case I

int a = 10, b = 3;

float c = a / b;

Output $\rightarrow 10 / 3 \rightarrow 3$

cast

type operator

Case II

int a = 10, b = 3;

float c = (float) a / b;

(float) expression
parenthesis before algebraic

Output $\rightarrow 10 / 3 \rightarrow 3.33$
 $10.0 / 3.0$ Case III

int a = 10, b = 3;

float c = (float) (a / b);

Output $\rightarrow 10 / 3 \rightarrow 3 \rightarrow 3.0$

Type Cast Operator

The type cast operator converts the data type of the expression to the type specified by the type-name.

KEYWORDS

The keywords are words whose meaning has already been explained to the C compiler.

3.2 Keywords

auto	- double	- int	struct
break	- else	- long	switch
case	enum	- registers	typedef
- char	- extern	- return	union
const	- float	- short	- unsigned
continue	- for	- signed	void
default	goto	- sizeof	volatile
do	if	static	- while

Character Input & Output

getchar()

To read a single character as input we use [getchar()] function.

char ch;

printf("Enter a character.");

ch = getchar();

printf("Entered character: '%c\n'", ch);
return 0.

Output

→ Enter any character: A
Entered character: A

putchar()

To output a single character we use the [putchar()] function.

char ch;

printf("Enter any character.");

ch = getchar();

printf("Entered character: ");

putchar(ch);

return 0;

Output

→ Enter any character: A
Entered character: A

Formatted Input and Output

- 1) `printf()` : used for displaying a single or multiple values in the form of output for the user end at the console.
- 2) `scanf()` : this is used for reading a single or multiple values in the form of input from the user end at the console.
- 3) `sprintf()`,

Format Specifiers

<code>%t</code>	tab space
<code>\n</code>	new line
<code>%d</code>	Signed integer
<code>%c</code>	character value
<code>%f</code>	Floating point value of a float
<code>%lf</code>	Floating point value of a double
<code>%Lf</code>	long double
<code>%s</code>	string

`gets()` : used for reading a string from a user.
`puts()` : prints a string taken from the user input on the console.

Scanf() - Syntax

`scanf ("%d" & variable name)`

int var;

`scanf ("%d" & var);`

+ : whitespace handling
+ : decimal handling

If - Else Statements

Syntax

```
if ( condition )
```

```
task 1  
task 2
```

```
}
```

```
}
```

to give more options than 2

```
int x = 0;
```

```
if (x == 0)
```

```
pr --- -
```

```
else if (cond. 2)
```

```
pr --- -
```

```
else if (cond. 3)
```

```
pr --- -
```

```
else
```

```
pr --- -
```

Syntax

Switch (x)

```
case 1: printf ("...");  
break;
```

```
case 2: printf ("...");  
break;
```

```
case 3: printf ("...");  
break;  
default: printf ("...");  
break;
```

SWITCH

A control instruction that allows us to make a decision from the number of choices.

For Loops

Syntax

```
for (initialization; condition; increment/decrement)
{
    Statement;
}
```

Example :

```
for (i=3; i>0; i--)
{
    print(b);
}
```

while loops

Syntax

```
while (expression)
{
    Statement;
}
:
:
:
}
```

Example

```
int i=3
while (i>0)
{
    print(1);
    i--;
}
```

Do while loops

Syntax

```
do
{
    print("ab... ");
}
while (i>0);
```

The difference between while and do while

We use do while, where want the body of the condition to execute once first, then check the condition and then start a loop.

Break

Used to terminate from the loop.

Continue

It forces to executes the next iteration of the loop.

Functions

Function is basically a set of statements that takes inputs, perform some computation and produces output.

Syntax

Return-type function-name (set-of-inputs);

Why do we need functions?

1. Reusability: Once the function is defined, it can be reused over and over again.
2. Abstraction: If you are just using the functions in your program then you don't have to worry about how it works inside!

Function Prototype: declaring the properties of a function to the compiler.

Eg: int fun (int, char);

Properties of a Function

- Name of the function: 'fun'
- Return type of function: 'int'
- Number of parameters: 2
- Types of parameters 1 & 2: 'int' and 'char'
